FLOOD HAZARD MAPPING, INSURANCE & PROPERTY IMPACTS

A Pattern of Transparency Failures, Institutional Arrogance and Self-Protection Across New Zealand Councils

Media Briefing Document – July 2026

Executive Summary

Multiple New Zealand councils are systematically resisting transparency on how flood hazard mapping and coastal hazard information are affecting property values, insurance availability, and local rating bases. This resistance includes imposing substantial charges, lengthy extensions, and claims of 'substantial collation' — even after requests have been refined.

At the same time, many councils and some central government-aligned commentators publicly emphasise 'climate change' and managed retreat messaging while appearing reluctant to openly discuss chronic underfunding and maintenance failures in flood protection infrastructure. Residents in some areas have reported discovering their properties were on flood hazard maps only at public meetings, with limited prior proactive notification.

The Reserve Bank of New Zealand has stated that it has issued no guidance to banks on lending to older housing stock, has conducted no analysis on how its climate and natural hazard frameworks affect such lending, and holds no data on the market impact. Banks appear to be applying broad, area-based lending restrictions rather than individual property assessments. New Zealand has one of the oldest housing stocks in the OECD.

Co-governance arrangements have introduced private trusts and entities with voting rights on council decision-making bodies related to natural hazards and managed retreat. These entities are not subject to the same transparency obligations as elected councils. Proposed local government amalgamations risk making accountability even harder.

This pattern of arrogance, lack of accountability, and riding roughshod over communities undermines public trust and leaves ratepayers bearing the consequences through falling property values, rising insurance costs, and uncertainty. Without major changes, the impacts will become severe for hundreds of thousands of New Zealanders over the next 5–10 years.

The Core Problem

Flood hazard mapping is necessary. However, when councils release or update this mapping without proper transparency about its real-world consequences, it creates significant harm. Homeowners can face sudden drops in property value, difficulty obtaining or affording insurance, and uncertainty about their long-term ability to stay in their homes.

Despite this, several councils have made it difficult and expensive for the public to obtain clear information about these impacts. Tactics include high LGOIMA charges, repeated extensions, and framing resistance around request volume rather than engaging with the public interest.

A Pattern of Resistance, Arrogance and Self-Protection

This behaviour is not isolated. Similar patterns have emerged across multiple councils:

Tauranga City Council (July 2026): Proposed a charge of $1,836 for information on how flood hazard mapping affects property values, sales, insurance, and the rating base. Stated that work would not proceed without agreement to the charge.

Hawke’s Bay Regional Council: Multiple extensions on LGOIMA requests relating to coastal hazards and climate risks. A class action has been approved against HBRC over

flood management failures in Wairoa (June 2024 floods), with allegations including failure to open the river bar in a timely manner despite local knowledge.

Auckland Council & Ministry for the Environment (MCERT): Repeated scope objections and demands for significant narrowing on requests concerning spending on managed retreat and comparative analysis of infrastructure versus retreat pathways.

Inadequate Notification Practices: In some areas, residents have reported discovering their properties were included on flood hazard maps only during public meetings, with limited proactive notification beforehand. This approach has been described as callous and has left communities feeling blindsided and disrespected.

Reserve Bank Position and Blunt Lending Practices

In July 2026, the Reserve Bank of New Zealand responded to an Official Information Act request stating that it has not issued any guidance to registered banks on lending to older housing stock (including pre-1940s villas and bungalows), has not conducted any analysis on the impact of its climate-related financial risk and natural hazard frameworks on such lending, and does not hold data on the number or proportion of loan applications for properties with hazard notations that have been declined or restricted. The RBNZ also stated it has not assessed the broader market impact of these lending practices on housing supply, affordability, or liquidity.

New Zealand has one of the oldest housing stocks in the OECD, with a very large proportion of existing homes built before modern insulation standards (pre-1978) and a significant number of pre-1940s villas and bungalows. Blanket or area-based tightening of lending on 'older housing stock' or properties with hazard notations therefore has the potential to affect a substantial segment of the national housing supply.

There is growing evidence that banks are applying broad, postcode-level or area-based lending criteria rather than conducting individual, property-by-property risk assessments. Residents are reporting that they are discovering they are on hazard maps at public meetings, only to then find that banks are applying blanket lending restrictions to entire areas rather than assessing properties on their individual merits (roof condition, maintenance history, actual flood risk mitigation, etc.). This blunt approach compounds the problems created by councils' lack of transparency around hazard mapping.

The absence of central guidance, analysis, or oversight from the primary banking regulator on these practices represents a significant governance gap. When banks apply blunt, area-wide lending restrictions without transparent individual assessment, and when there is no regulatory visibility or direction on this, it creates reckless and destabilising conditions in the housing market — damaging homeowners, first-home buyers, communities, and ultimately the banks themselves through reduced market liquidity and increased systemic risk.

Co-Governance and Reduced Transparency

Co-governance arrangements have introduced private trusts, iwi entities, and incorporated bodies with voting rights on council committees and decision-making processes related to natural hazards, planning, and managed retreat. While these arrangements are presented as partnership models, many of these entities operate as private trusts or societies and are not subject to the same transparency and accountability obligations as elected councils under the Local Government Official Information and Meetings Act.

This creates a layer of decision-making power over issues that directly affect private property rights, insurance outcomes, and long-term community futures, with significantly reduced public scrutiny. When these entities advocate for or influence managed retreat pathways without being required to disclose the same level of information as councils, it further compounds the existing pattern of opacity around whether retreat is being driven by genuine risk assessment or other considerations.

The combination of council resistance to transparency, blunt bank lending practices, Reserve Bank inaction, and co-governance entities operating with reduced public accountability creates multiple layers of governance with limited visibility for ratepayers. This is a structural problem that makes genuine public oversight increasingly difficult.

Predictable Consequences if Current Trajectory Continues

If the current lack of transparency from councils, blunt lending practices by banks, absence of meaningful oversight from the Reserve Bank, and reduced accountability in co-governance structures are not addressed, the following outcomes are predictable and increasingly likely over the next 5–10 years:

Accelerating Insurance Retreat: Insurers will continue to withdraw cover or impose unaffordable premiums in high-risk and hazard-noted areas. Full or partial insurance retreat in many coastal and flood-prone zones is likely by the early 2030s.

Properties Becoming Unmortgageable: As insurance becomes unavailable or prohibitively expensive, banks will be unable or unwilling to lend on affected properties. This will trap existing owners and shut out first-home buyers from large segments of the housing market.

Sharp Declines in Property Values and Liquidity: Properties in hazard zones will face significant devaluation and become difficult to sell. This will particularly affect owners of older housing stock and those in areas with hazard notations.

Rating Base Pressure on Councils: Councils will face declining revenue from affected areas at the same time as demand for infrastructure protection or managed retreat support increases.

Social and Community Harm: Families will experience financial stress, mental health impacts, and difficult decisions about whether to stay in or leave communities they have lived in for generations. By the early 2030s, without intervention, many communities could face significant disruption and displacement pressure.

These outcomes are not speculative. They are the logical and predictable consequences of the current trajectory. This document records these warnings in advance so that when these events occur, there can be no credible claim that the risks were unknown or unforeseen.

Legal Action as Evidence of Serious Issues

In Hawke’s Bay, a class action against the Regional Council over the 2024 Wairoa floods has been approved by the High Court. The case centres on allegations of failure to properly manage the Wairoa River bar and flood protection infrastructure. This demonstrates that the issues around flood management, transparency, and accountability are serious enough to result in formal legal proceedings.

Public Interest and Impact

Ratepayers and homeowners have a clear interest in understanding how hazard mapping and council infrastructure decisions affect their properties, insurance costs, and the long-term financial sustainability of their communities. When councils make it expensive or difficult to obtain this information, and when they fail to proactively and clearly notify residents about hazard mapping changes, it amounts to riding roughshod over the people they are meant to serve.

Property values are being impacted, insurance is becoming harder or more expensive to obtain, and communities are being left in limbo — all while some councils and commentators continue to push retreat narratives without honest reckoning with the infrastructure funding failures that have contributed to the current situation.

Conclusion

New Zealand councils — and in some cases central government messaging — are increasingly using charging, extensions, scope objections, inadequate notification practices, and structural reform to limit scrutiny of how flood hazard mapping and managed retreat pathways are affecting communities. This pattern of arrogance, lack of accountability, and riding roughshod over ratepayers, combined with heavy public emphasis on climate narratives while avoiding open discussion of infrastructure underfunding, represents a significant transparency and accountability failure.

The public deserves straight answers and proper engagement — not bureaucratic barriers, surprise map inclusions, deflection onto climate change alone, or reforms that make accountability harder. The current approach is arrogant, unaccountable, and ultimately unsustainable. It needs to be exposed and challenged before the consequences become even more severe for hundreds of thousands of New Zealand families and communities.
